

Metodología para diseñar casos de prueba

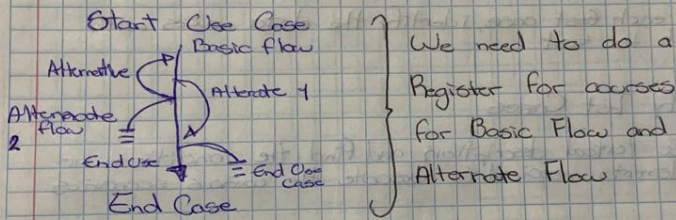

The important part of a case for generating test cases in the flow events,

The two main parts } what normally happens when the use case is performed

Basic flows of events

Alternate flows of events

Cover behavior of an optional or exceptional character relative to ~~form~~ normal behavior, and variations of the normal behavior

Use Case Scenarios

The basic flow would be one scenario

The basic flow plus alternate flow 1A would be another

The basic flow plus alternate flow 2A would be a third and so on

All possible scenarios, beginning with the basic flow and then the alternate flow

Scenario 1	Basic Flow		
Scenario 2	Basic Flow	Alternate Flow 1	Alternate Flow 2

Generating Test Cases

Is a set of test inputs, execution conditions and expected results, Test cases are necessary to verify successful

3-steps process for ~~generate~~ generating test cases

- 1) For each use case, generate a full set of use case scenarios
- 2) For each scenario identify at least one test case and the conditions that will make it "execute"
- 3) For each test case, identify the data values with which to test

Identify Test Cases

Use case textual description and find the conditions or data elements required to execute the various scenarios

Identify Data Values to Test

Should be reviewed and validated to ensure accuracy and to identify redundant or missing test cases
